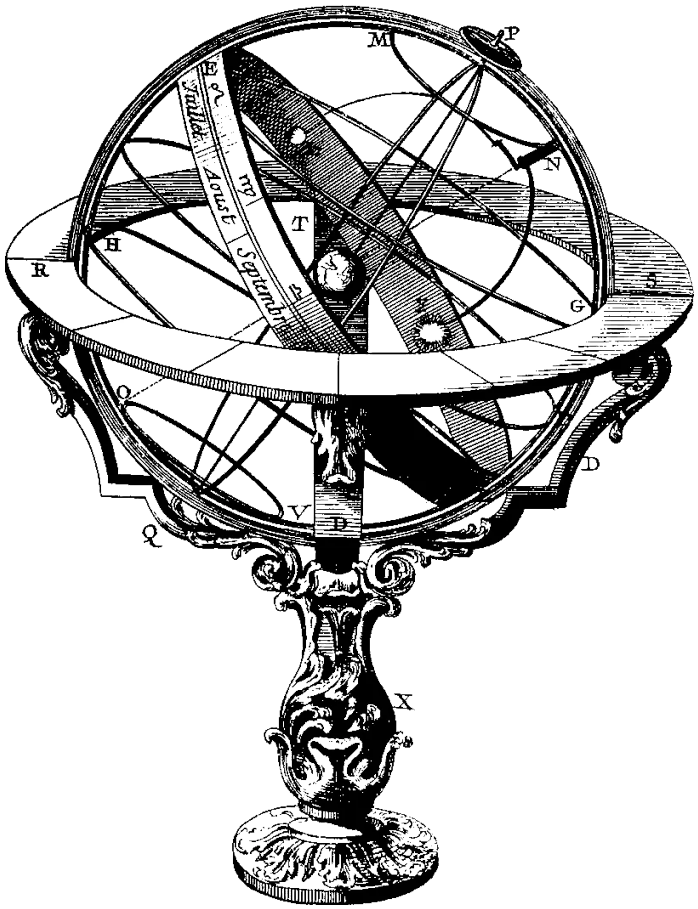
DEEP WORK

Solstice Against the Grain

Reason, Intuition, and the Politics That Hide Inside Them

ESCHATOLOGY REPORT

JAN 21, 2026 • PAID



The solstice is one of those holidays that doesn't need marketing. It doesn't ne
committee or a branding guideline. It's just there, baked into the physics of be
on a spinning rock. The sun reaches its turning point, the arc stalls for a heart
wheel clicks over, and everything: plants, animals, people who pretend they ar

animals quietly register it. Even if you don't "believe" in anything, you still live spinning sky.

And that's why it's such a great pagan celebration. Not because it's edgy or aes "alternative," but because it reminds you of a kind of participation that the do culture doesn't know what to do with. The culture we're embedded in has mad paragon out of reason. Reason is the approved lens, the credentialed instrume thing you're supposed to trust publicly even when you're making most of your decisions privately by some other method entirely.

Thanks for reading! Subscribe for free to receive new posts and support my work.

So, in the spirit of solstice mischief, I wanted to talk about reason and intuitio the politics that attend each. Not in a scolding way. More like: let's pick this m up, turn it over, and see what's written on the bottom.

The Two Great Masks of Reason

Reason, traditionally speaking, has two canonical forms. They're called deduct induction, and if you want to be tidy about it, you can cram most "rational" pr into one of those boxes.

Deduction

Deduction is what people mean when they say "reasoning from first principles starts with something you can't prove, agrees to treat it as given, and then bui outward from there.

- Start with something you can't prove.

- Agree to treat it as given.
- Build outward from there.

The cleanest example is Euclid. “Parallel lines never meet.” You can picture ra tracks in your head, run your mind along them to infinity, and in that imagina inspection of an infinite railroad you never witness the rails crossing. So you a the axiom as true, and from that moment on you can build an entire geometric cathedral with stained glass and flying buttresses, all perfectly aligned, all see inevitable. Deduction feels aristocratic because it is. It’s the kind of reasoning looks like it belongs in marble.

But what’s worth noticing is that deduction isn’t confined to mathematics. Th structure shows up in theology and metaphysics, which is why they’ve always the prestige of math. A generic theology can proceed as follows: God exists, ar loves us. You don’t prove those first principles. You assent to them. Then dedu goes to work producing an explanation for why we are separated, what must b why suffering exists, what salvation means, and so on. The machine is the sam only difference is what you’re feeding into it.

And that difference matters, because it exposes the hairline fracture in deduct mathematics the axiom feels secure because it’s presented as self-evident. “Yo it’s true.” It appeals to a kind of inner obviousness. Nobody can actually prove lines never meet” in the ultimate sense, but the imagination yields a convincir demonstration, and we treat that as enough. When you move into theology, th principles don’t appeal to obviousness; they appeal to desirability. They appea hope. “God exists.” “God loves us.” We might want those to be true, but we do “see” them the way we see rails receding toward the horizon.

So deduction, especially in the deeper matters, is never as clean as it pretends depends on the axiom. It depends on what you’re willing to grant at the begin

is a machine that produces certainty, but the certainty is only as good as the unprovable thing you agreed to stand on. That's not a moral failing. It's just th structure. The marble temple has sand under it, and the sand is called assent.

Induction

Now, induction is the other form, and to my mind it's the more interesting on because it's the form that gets its hands dirty. It doesn't begin with pristine fi principles. It begins in the world. It begins with repetition.

- Observe.
- Repeat.
- Generalize the pattern into a "law."

You hit the water with a shovel and it splashes. You do it again and it splashes it a thousand times and it splashes. Then you make the leap: shovels can be us make water splash. The premise is observation. The engine is repetition. The is a law.

Philosophers used to hate this, at least the ones with an Aristotelian aesthetic it doesn't have mathematical elegance. It isn't "pure." It's messy. It's down the among the wet floors and the broken glass, looking at things, counting things, things again. But out of this mess comes modern science. Induction is the pro heart of experiment, and experiment is the great tool of the age.

Still, induction has a secret assumption hiding inside it, and that assumption i time. Induction presumes that time is invariant enough for repetition to mean something. If A precedes B in a thousand cases, then A will likely precede B i thousand-and-first. It's probabilistic. It works not by certainty but by moment the accumulated weight of pattern.

And here's where it gets interesting, because the assumption is true in some d and wildly unreliable in others. It's true for the grossest phenomena, the ones behave like clockwork. If you're studying orbits or certain chemical processes predictable mechanical systems, induction gives you real power. It lets you an outcomes. It lets you build bridges and cure infections and land probes on roc don't even have air.

Where Induction Goes to Die: The Domain o Living

But when you lay induction against the background of lived experience, it star out. The most interesting cases are not shovel-hits-water. The most interestin are love affairs, divorces, lawsuits, religious conversions, political upheavals, t things that remake you. In those domains, induction is a poor guide. One love does not explain another. One marriage doesn't illuminate another in the way illuminates a falling object. One revolution does not neatly model the next. Yo always extract generalizations, but when you live through these events what y away is their weird specificity, their irreducibility, the sense that what just hap could not have been predicted by any amount of prior pattern recognition.

So induction is excellent at predicting what "goes around and comes around," reality is not composed only of things that go around and come around. A very portion of life is made of singularities, and the mind keeps bumping into them knee into the corner of a table.

The Political Nerve

Now the political nerve comes in here, because science doesn't simply say "we tool among tools." It doesn't present itself like Buddhism or Taoism or tarot o

which tend to admit they are paths, styles, temperaments. Science claims a sp
status. It claims epistemic preeminence. It says, in effect, we are not an ideolo
are the meta-system. We shall weigh all other systems in our scales.

That claim is not philosophy. That claim is politics.

Because the grounds for it are thin. Deduction rests on axioms you cannot ulti
prove. Induction rests on temporal invariance that holds strongly only in a cer
band of phenomena. Those are useful tools, but they are not cosmic crowns. W
treat them like crowns, you're no longer doing inquiry. You're doing governan

Which is why, in the context of a solstice celebration that is even faintly self-a
feels appropriate to commit a small act of heresy: to attack reason, or at least t
the cultural habit of enthroning it. Reason is valuable. But a tool becomes tyra
the moment it claims to be the only legitimate tool.

What Remains When Reason Loses Its Crow

And if you take the crown off reason's head, what's left?

Intuition.

Intuition is the faculty that makes the dominator culture nervous because it d
produce a transcript. It comes to an answer and leaves no trail. You know som
but you can't always reconstruct the chain of argument that got you there. It's
"irrational" in the sense of being stupid. It's pre-rational or trans-rational, in t
that it operates as a whole-organism mode of knowing. It processes foregroun
background at once. It recognizes patterns without having to narrate them.

This is why it's always portrayed as:

- Vague
- Feminine
- Unreliable

That's not just a descriptive assessment; it's a political demotion. If your socie organized around auditability, justification, bureaucracy, and formal power, th modes of knowing that can't be audited or justified on command must be trea suspect. Intuition refuses the paperwork.

But in the felt domain of living, intuition is what most people actually run on, including those who insist they're "not intuitive." They may use reason to defe choices after the fact, to make them socially presentable, to convert them into arguments that will survive in the conference room, but the choice itself is oft in the body, in the gut, in the field sense of "this is right" or "this is off." Intuit not an exotic mystical gift. It's the organism navigating complexity in real tim

And if you want a Western corollary to the Dao, it's this. The Dao is often pres an Eastern concept hovering at the edge of intelligibility, a thing you can't qui in your hand. But Western thought has its own version: intuitionalism, the abi sense constraints and opportunities in the moment and move with them. It's f intelligence. It's situational wisdom. It is knowing without necessarily being a prove.

At this point you might feel the classic objection rising: if we dethrone reason barbarism follow? Doesn't madness rush in? Yes. It can. But notice the sleight The fear is that without reason we will have no order, as though the only kind is the kind a committee can certify.

Chaos is not the absence of order. Chaos is the womb of order.

That line still earns its keep. But it works better when it's a spice, not the who

So that's act one. Reason has two masks, both useful, both limited. Their cultu supremacy is not a philosophical inevitability but a political arrangement. Intu the underclass faculty that actually guides us through the domains that matter precisely because those domains are not reducible to repeatable laws.

Act Two: Evolution and the Real Scandal

Act two begins in the nineteenth century, when science itself (without quite a it) is forced to confront the inadequacy of its own idol. This is happening, fam a world of Victorian gentlemen with beards to their belts and a furniture aest repressed that pianos wore pants. So the insight arrives in disguise.

It arrives as evolution.

We're taught that the scandal of evolution was that humans descended from a That's the tabloidy version. That's the story for people who like their intellectu history with clear villains and heroes. The real scandal, the one that brought t down, was teleology. Darwin's outrageous assertion was not "you have animal ancestors." It was "nature can be accounted for by processes without purpose."

Trendlessly fluctuating. That phrase is like cold water. It means: no plan, no h end, no cosmic intention guiding the process. Random variation plus environ selection pressures can generate plants, animals, and eventually a creature tha operas and builds atom bombs and asks what all of this means.

That was the real fight, because it struck at the need for God as an efficient ca the machinery of the universe. It wasn't primarily an insult to human dignity. attempt to remove intention from the structure of being.

Wallace, Darwin, and the Fever on Ternate

And then, beautifully, the story becomes even weirder because one of the co-discoverers of natural selection, Alfred Russel Wallace, arrives at the idea in a Wallace is not a gentleman scientist. He is a field naturalist, a working-class n a sprawling curiosity. He's collecting specimens in the Malay Archipelago, he malaria, and at the height of the fever he scribbles down what appears to him afterward to be a coherent solution to the problem of the species. He sends it Darwin, the great cautious gardener of Down House, who has been circling th idea for decades.

Darwin reads the letter and, depending on which telling you prefer, either pal or simply experiences the internal equivalent of being struck by lightning. Th he has been incubating has arrived in his mailbox from the jungle. His friends a joint presentation, and history remembers Darwin as the name on the banne

Wallace, meanwhile, remains Wallace: polymath, socialist, spiritualist, fascina the paranormal as well as by biogeography and electricity and anthropology. A philosophical fault-line shows itself right there. Wallace cannot take the final teleology. He can accept the mechanism of natural selection, but he cannot be blind processes fully account for the eruption of human consciousness. He ser aim, an arc, an omega point toward which creation moves, however unsteadily

And this is where it becomes hard to be honest, because many of us, if we stop performing for the culture, feel the same. Our intuition wants to be in Wallace Not necessarily in a naive "everything is for the best" way, but in the sense tha universe does not feel like pure accident. It feels like something is happening. like novelty is not merely random noise but a persistent tendency, a kind of de leaning.

The Irony: Evolution Smuggles Back the Forbidden Id

Here's the delicious irony. Evolution, which in part tried to banish teleology, s back the forbidden idea under a different name. It smuggled back progress. Be Darwin, Western thought often pictured nature as a static Great Chain of Beir to angels to man to animals to plants to minerals, fixed in place. Darwin turns ladder into an escalator. He adds time. He implies ascent, or at least increased complexity, increased differentiation, increased novelty.

And once you have that, you've reintroduced an ancient heresy. You've returne modern language, to an alchemical intuition. The alchemists believed nature i to perfect itself, that lesser metals slowly become gold, and that the alchemist' to compress time, to catalyze what nature is already doing in secret. Modern s laughed the distillation apparatus out of the room. Then evolution walks in we lab coat and quietly reinstates the notion that time has a direction.

Social Darwinism: The Vulgarization of a Subtle Thir

Now, at this point, the concept gets vulgarized. Social Darwinism takes the es and turns it into a boot on a neck. It says nature is about domination, therefor domination is justified. Survival of the fittest becomes a moral slogan for class oppression. This is not only ethically grotesque; it's biologically lazy. It's natur understood through the eyes of a nineteenth-century empire.

If you actually look at living systems as networks of mutual dependence, you s different principle at work. Cooperation is not an exception. It's the fabric. Interdependence is not sentimental. It's structural. The most "successful" spe not necessarily the one that can dominate all others; it's the one that makes its indispensable. Bacteria are the obvious example. No higher life can operate wi them. The idea of bacteria going extinct is almost comical. They have built the

into the foundations of the whole show.

So if you insist on learning morality from nature, perhaps the lesson is not cor
Perhaps the lesson is making yourself necessary.

Evolution Beyond Genes: The March Out of Chaos

And then the argument extends beyond biology, whether the purists like it or
Someone will always say, “If it doesn’t involve genes, it ain’t evolution.” As thc
word can be owned. As though a concept can be fenced. But the concept has a
escaped. Evolution, broadly understood, is the march out of chaos into order,
connectedness, self-expression, and eventually self-reflection.

You can see it at multiple levels:

Physical: Atoms settle into stable configurations → Chemistry evolves toward
molecules → Polymers arise

Pre-life: Self-organizing energetic systems appear

Biological: Replication → Motility → Nervous systems → Minds

Symbolic: Language → Ritual → Myth → Dance → Art

Social: Technology → Institutions → Ideologies → Entire realities constructed
shared hallucination and paperwork

And yes, eventually, the writing of operas.

When you look at that arc, it’s hard not to sense a progressive tendency. Not a
line, not a guaranteed moral improvement, not a benevolent plan, but a stubbc
leaning toward complexity and novelty, toward richer forms of relation, towar

order patterns that can reflect on themselves.

Which lands us back in the present, in the thing we all half-know:

- We are living in compressed time.
- Everything speeds up.
- Consequences bunch together.
- The old inductive comfort that tomorrow will resemble yesterday begins t the domains where it always fails first, namely the domains that involve m power, identity, and collective fate.

Solstice as a Lesson in Knowing

So the solstice becomes more than a seasonal marker. It becomes a reminder c we know what we know. Reason is a splendid tool, but it is not an emperor. De builds cathedrals out of unprovable axioms. Induction builds machines out of repeatable patterns, and those machines are real and useful and sometimes lif but neither form earns the right to declare itself the final judge of reality.

That "epistemic preeminence" posture is governance dressed as neutrality.

And intuition, the faculty the dominator culture downgrades, is not a hazy orr It is often the primary navigation system for the very domains that matter mos how organisms move through complexity when the map runs out.

Reason belongs in the toolbox. Intuition belongs at the helm.

Not always. Not blindly. Not as a new priesthood. But as a restored balance, a legitimation of the kind of knowing that can't always justify itself in court yet manages, again and again, to be the difference between walking into the right

and the wrong one.

The solstice doesn't argue with you. It turns anyway. And maybe that's the dee lesson here. There are truths you can prove, truths you can predict, and truths only participate in. The modern world worships the first two. The solstice qui reintroduces the third.

And if that's "against the grain," good. The grain isn't always your friend.
